Consequently, the system can maximize the number of pages that can be printed at a maximum amount of , while maximizing the number of pages that can be printed on , and minimizing the number of pages that have to be printed on . An example of this operation is illustrated in Fig. [fig:sequencing]. In the operation illustrated in the figure, we consider the case where the user wants to print pages 1, 2, 4, 5, 6, 8, 9, 10, 11, 12 and 13, however the user only has on the printer. Therefore, the task is to print pages 1, 4, 5, 6, 8, 9 and 11, leaving the remaining pages to be printed on the second run of the printer. [Sequencing a printing task with a task manager. The diagram shows the sequential printing of pages 1, 2, 4, 5, 6, 8, 9, 10, 11, 12 and 13. The page 1 has been printed, but the remaining pages have to be printed on the second run of the printer.] [data-label="fig:sequencing" ][width="0.8\linewidth"] The sequential mode of operation of the page task manager consists of the following steps: - At the beginning of the execution of the page task manager, it starts listening for user commands through a Command Line Interface (CLI) that was described in section [sec:commands]. - When the user enters a printing task that consists of pages that can be printed in the sequential mode, the page task manager performs the step [step:sequentialrequest] and asks the task manager to sequentially print the printing tasks. - After the execution of the sequential mode has started, the user can enter more printing tasks that consist of pages that can be printed in the sequential mode. The proposed mechanism for optimizing the parallel printing is only applicable for printing tasks that consist of pages that can be printed sequentially in the printer, since it increases the number of pages that can be printed on the printer and decreases the number of pages that have to be printed during the second run of the printer. To evaluate the performance of the proposed mechanism, we performed a number 82157476af
